

AI PoC Triage and Adoption Planner

A compact prototype for AI transformation teams: evaluate internal AI ideas, decide whether they are ready for a controlled proof-of-concept, and define the adoption plan, success metrics, and guardrails needed before scaling.

What it assesses	Business impact, delivery feasibility, responsible AI / operational risk, and adoption readiness.
What it generates	Stage-gate recommendation, four-week PoC plan, controls, success metrics, adoption materials, executive summary, and LLM prompt pack.
Why it matters	AI ideas often fail between prototype and adoption. This tool makes the decision process explicit, measurable, and safer for regulated business settings.

Product Flow

1. Define the use case, target users, workflow and data types. 2. Score impact, feasibility, risk and adoption. 3. Receive a stage-gate recommendation: fast-track controlled PoC, controlled pilot with governance gate, pre-PoC discovery, or backlog. 4. Generate the PoC plan, controls, measurement plan and communication prompts.

Why this fits Computershare

Computershare's AI insights emphasise reusable frameworks, short low-risk experimentation, leadership alignment, responsible AI, clear success measures, training, and a 'test, measure, analyse and repeat' approach. This prototype follows that mindset: it turns promising AI ideas into governed PoCs with explicit value, feasibility, controls, adoption needs and measurement before scale.

Example Use Cases

The prototype includes sample scenarios relevant to financial administration: Copilot-assisted shareholder query summaries, corporate-actions obligation extraction, employee share-plan FAQ support, and internal AI adoption reporting.

AI Usage Demonstrated

The app demonstrates AI-assisted product development, prompt design, structured scoring, risk-aware workflow design, and non-technical communication. It treats AI as a tool inside a controlled business process rather than an unchecked answer generator.

Technical Components

Standalone HTML/JavaScript app for easy review, Python scoring engine for reusable logic, optional Streamlit app for deployment, JSON sample cases, and an application note explaining the design choices.

How I would extend it

With enterprise access, I would connect it to approved Copilot/LLM tooling, add authentication, maintain an AI use-case register, log reviewer decisions, and connect adoption metrics to internal reporting dashboards.
